Chapter 1 — Introduction

What Sigalytic V2 Is

Sigalytic V2 is a decision intelligence platform built around a single idea: markets move in campaigns, not random ticks, and the classic tape-reading disciplines of Richard Wyckoff, David Weis, and Jesse Livermore — reading accumulation, effort-versus-result, and the line of least resistance — can be run continuously, at scale, across the entire market, by software instead of by a single trader watching one chart at a time.

Concretely, the platform does three things at once. First, it continuously scans roughly one thousand US equities, scoring each one on real price and volume behavior — trend structure, relative strength, volume pressure, and short-term expansion — to answer a simple question: which symbols deserve attention right now? Second, it identifies and tracks "campaigns": specific symbols that have shown genuine structural evidence of accumulation or distribution, and follows each one through a lifecycle (from a fresh spark, through confirmation, survival, expansion, and eventual maturity or failure) rather than treating every price move as an isolated event. Third, it tracks the trader — logging trade plans, entries, and exits, and building a behavioral profile of how a person actually trades, separate from how the market is behaving.

A second, independent layer — the Intelligence Change Detector — runs a deeper, once-nightly Wyckoff/Weis/Livermore evaluation against every actively tracked campaign and flags any case where the deeper analysis meaningfully disagrees with the live radar score, so a promising-looking symbol on the surface can be double-checked against a more rigorous read before it earns real attention.

Who This Guide Is For

This guide is written for subscribers using the Sigalytic V2 platform. It assumes familiarity with basic market concepts — price, volume, support and resistance — but does not assume any prior experience with Wyckoff, Weis, or Livermore methodology specifically; the Glossary in Chapter 4 defines every term used on the platform in detail.

How This Guide Is Organized

Chapter 2 covers getting started and the overall shape of the interface. Chapter 3, Core Concepts, is the heart of this guide — it walks through every tab in the platform, and every meaningful screen or panel within each tab, explaining what it shows and how to read it. Chapter 4 is a detailed glossary of every trading term and abbreviation used on the platform. Chapter 5 covers support and feedback.

Chapter 2 — Getting Started

Accessing the Platform

The platform runs in any modern desktop web browser. It is optimized for screens 1200 pixels wide or larger.

Logging In

Sign in with your account email and password. Your session persists across tabs and page reloads while you remain logged in; the Log Out button in the top-right corner of the header ends your session.

Navigating the Interface

The header runs across the top of the screen and contains the Sigalytic logo, live feed status badges (LIVE / data source / tick counter), a symbol input field and Load Symbol button, the live price display, and the timeframe selector (1m, 5m, 15m, 1H, 1D, 1W).

Below the header is the tab navigation bar. The platform is organized into the following tabs, covered in detail in Chapter 3:

- Home — landing/overview screen.
- Command Center — the primary real-time single-symbol trading environment.
- Campaign Intelligence — the full list of actively tracked campaigns and their lifecycle state.
- Live Feed — raw live price/volume data for the currently loaded symbol.
- Performance — a lightweight snapshot of the current symbol's setup.
- Behavioral Intelligence — your personal trading behavior profile.
- Import History — upload and reconstruct trade history from broker statements.
- Radar Screen — the continuous, universe-wide opportunity scanner.
- Scoreboard — a live leaderboard of recent signal outcomes.
- Intelligence Change Detector — the nightly deep-analysis comparison against the radar score.
- Portfolio — an aggregate view across all active campaigns.
- Journal — your logged trades and behavioral grades.
- Status — a technical, read-only dashboard of data freshness and system health.
- Billing — manage your subscription plan.
- Preferences — customize alert types and display behavior.
- Admin — restricted system administration (visible only to administrators).
- Setup — technical configuration and deployment details.

Chapter 3 — Your Daily and Weekly Routine

The platform is designed to fit into a repeatable rhythm rather than be checked at random. This chapter lays out a practical, tab-by-tab routine — what to look at, and in what order — for a typical trading day and a typical week. Treat it as a starting template, not a rigid script.

A Typical Daily Routine

Before the Open (Pre-Market)

- Check the Status tab first. Confirm Radar Refresh, Campaign Refresh, and Evidence Refresh all show recent timestamps, and that Radar Cache reads a live mode rather than a fallback state. This takes ten seconds and confirms the rest of your routine is working from current data.
- Check the Intelligence Change Detector for anything the nightly deep-evaluation audit flagged overnight. Any symbol you already hold, or were watching, that shows a Major Downgrade deserves a second look before the open; a Major Upgrade on a symbol you weren't watching is worth adding to your radar.
- Scan Campaign Intelligence's Yellow Alert banner for genuinely new campaigns sparked in the last three days, and skim the SPARK and CONFIRMED tabs for anything with an already-strong ODS.

At the Open and Through the Session

- Open the Radar Screen and sort by readiness. The Top Opportunities section is designed to be the first thing you look at — it surfaces the highest-readiness setups with their full evidence card already assembled.
- When something on the Radar Screen or the Intelligence Change Detector earns a closer look, load it into the Command Center. Check the Trade Card and Price Ladder, and — if options data is available — the gamma overlay on the chart, before forming a view.
- Before entering any position, fill out the Plan Trade panel: direction, entry, stop, target, size, and a short note on your thesis. Click Save Plan, then Enter Trade once you actually take the position. This is what makes your Behavioral Intelligence profile meaningful later.
- Periodically check the Portfolio tab during the session to see your aggregate exposure across active campaigns, and to catch any new conjunction exit signal on a position you're already in.

At the Close and After Hours

- Log exits for anything you closed during the session, through the same Plan Trade flow you used to enter.
- Glance at the Scoreboard for a sense of how the session's signals played out in aggregate.
- The Intelligence Change Detector's deep audit runs once nightly (12:30 AM UTC); its results will be waiting for you at the start of the next day's pre-market check.

A Typical Weekly Routine

- Start of week: if you have new broker statements to reconcile, upload them through Import History so your Behavioral Intelligence profile reflects your complete trade history, not just what you logged manually.

- Mid-week: review Campaign Intelligence's Tier and ODS distribution across your full campaign set, not just the ones you're actively trading. Pay particular attention to any campaign that has drifted into MATURING or DISTRIBUTION_RISK — these are the candidates most likely to need an exit decision soon.
- End of week: open the Journal and review the week's completed trades alongside your Behavioral Intelligence composite and sub-scores. Read any adaptive warnings that fired during the week (Overtrading, Regime Mismatch, Loss Streak, or Plan Deviation) — these are personalized to your own history, not generic advice, and are worth taking seriously precisely because they are based on your own prior patterns.
- End of week: check Portfolio's total campaign count against the platform's 20-25 optimal range. A count well above that range is a signal to prune conviction, not necessarily a system malfunction — see the Glossary entry for Conjunction Exit Signal for one mechanism the platform uses to help with that.

Chapter 4 — Core Concepts

This chapter is organized by tab. Each section explains the tab's purpose, then breaks down every meaningful subscreen or panel within it.

4.1 Command Center

The Command Center is your primary real-time environment for a single loaded symbol. Type a ticker into the header's symbol field and click Load Symbol to bring up that symbol's live data, chart, and analytical panels.

Live Price and Chart

The live price panel shows the current real-time price, updated with every market tick, alongside the day's percentage change. The chart below it displays a candlestick view of the loaded symbol at the selected timeframe (1m, 5m, 15m, 1H, 1D, or 1W), rebuilding automatically whenever you change the timeframe or load a new symbol.

Gamma Flip Point, Call Wall, and Put Wall Overlay

When live options data is available for the loaded symbol, the chart overlays three structural levels derived from real gamma-exposure analysis: the Call Wall (the strike where call-side gamma exposure is heaviest, often acting as resistance), the Put Wall (the strike where put-side gamma exposure is heaviest, often acting as support), and the Gamma Flip Point (the level where net gamma exposure crosses from positive to negative). The region above the flip point is shaded to indicate a positive-gamma regime, where dealer hedging tends to dampen volatility and pin price; the region below is shaded to indicate a negative-gamma regime, where dealer hedging tends to amplify moves. These overlays display only on intraday timeframes (1m/5m/15m/1H), since on daily or weekly views they would cluster near the current price against months of unrelated history. If live options data is unavailable for a symbol, the panel falls back to a clearly labeled synthetic estimate and states the reason (for example, no options chain available for that symbol).

Trade Card

Summarizes the actionable setup for the loaded symbol: directional bias, current setup classification, and a suggested position-sizing posture. This is a decision framework, not a buy or sell signal — you are expected to define your own entry, stop, and target before acting on it.

Price Ladder

Displays the key structural price levels the system has identified for the current setup, including the trigger level (which must hold for the setup to remain valid) and the invalidation level (a close beyond which the thesis is considered compromised).

Plan Trade Panel

A structured framework for planning a trade before you take it: direction (Long/Short/Neutral), entry price, stop, target, size, and free-text setup notes. Clicking Save Plan records the plan to your Behavioral Intelligence profile without executing anything. Clicking Enter Trade begins live behavioral tracking of that position against the plan you stated — this is the primary mechanism through which the platform captures the data behind your Behavioral Intelligence profile (Section 3.6).

NOTE: Always fill out the Plan Trade panel before entering a position. Trades logged without a prior stated plan are still tracked, but are scored differently, since there is nothing to compare your actual execution against.

4.2 Campaign Intelligence

Campaign Intelligence is the full list of every symbol the platform is actively tracking as a "campaign" — a symbol with genuine, qualifying structural evidence of accumulation or distribution, followed through its lifecycle rather than treated as an isolated price move.

How a Campaign Is Created

A symbol only becomes a tracked campaign after clearing three separate thresholds simultaneously in the nightly discovery process: a birth score, a market-condition index (MCI), and a survival score. Most scanned symbols, on any given day, do not clear all three — a campaign being created is a deliberately selective event, not something that happens to every symbol in the universe.

Lifecycle States

Every campaign occupies exactly one of the following states at a time, shown as a tab filter at the top of the screen:

- SPARK — freshly discovered, earliest stage.
- SURVIVING — has held together past the initial discovery window.
- EXPANDING — showing active continuation/momentum.
- CONFIRMED — has cleared additional confirmation criteria.
- MATURING / DISTRIBUTION RISK — later-stage states where the system is watching for exhaustion or reversal risk.

Summary Tiles

At the top of the tab: Active (total campaigns currently tracked), Tier 1 and Tier 2 (the highest and second-highest conviction classifications, described below), Avg ODS (average Operator Dominance Score across all tracked campaigns), Avg ER / T1 / T2 / Fail (average expected return, and the average probability of reaching Target 1, Target 2, or the failure level), Avg RR (average reward-to-risk ratio), and a B/C count (how many campaigns currently carry a B or C outcome-quality grade).

The Campaign Table

Each row shows: the symbol and its Tier classification; current lifecycle state and age in days; ODS (Operator Dominance Score) and Decay (a measure of how much the original structural evidence has weakened); the next expected transition and directional bias; an outcome grade (A+ through W, described in the Glossary); expected return, expected MFE (maximum favorable excursion) and MAE (maximum adverse excursion); Target 1 and Target 2 probabilities; failure probability and reward-to-risk ratio; and a plain-language signal summary explaining why the row is scored the way it is.

NOTE: Some very young campaigns (typically under two weeks old) will show "ODS PENDING — INSUFFICIENT HISTORY" instead of a numeric score. This is correct, expected behavior — the Operator Dominance calculation requires enough historical evidence to be statistically meaningful, and a genuinely new campaign has not yet accumulated it.

4.3 Radar Screen

The Radar Screen applies a continuous, lightweight scoring pass to roughly one thousand US equities — a universe far too large to watch manually — and surfaces the highest-scoring, most "ready" setups in real time. It answers a different question than Campaign Intelligence: not "has this become a tracked campaign yet," but "which symbols deserve attention right now, before anything is confirmed."

How the Radar Score Is Built

Each symbol's composite score is a weighted blend of five components, computed directly from real, live price and volume data: Confluence (25%, how many bullish technical signals — price above VWAP, above moving averages, rising on above-average volume — currently line up), Expansion (20%, whether the symbol's trading range is compressing or expanding relative to its own volatility, and its proximity to a 52-week high), Relative Strength (20%, recent performance versus the symbol's own trend), Volume Pressure (20%, whether current volume is unusually heavy relative to its own recent average), and Behavioral (15%, a short-term intraday-behavior read, blended with a separate Behavioral Memory Engine score when available). Each component starts from a neutral baseline of 50 and is adjusted up or down by real, observed conditions — nothing on this screen is synthetic or placeholder data.

Opportunity Dashboard

The top of the tab shows summary tiles (Armed, Setting Up, Elite 90+, Avg Ready) and a "Top Opportunities" section highlighting the highest-readiness setups, each with a full evidence card: probability, edge ratio, expected return, grade, historical match count and confidence, the current behavioral transition (for example, "Compression → Expansion Attempt"), trigger and invalidation levels, and a plain-language "Why This Trade?" explanation.

Full Opportunity Radar Table

Below the highlighted opportunities, every scanned symbol appears in a sortable table: price, change percent, readiness score, composite score, grade, historical probability, expected return, edge ratio, lifecycle state, side, behavioral transition, setup type, and trigger/invalidation levels. The table is sorted by state (Armed first), then historical probability, then readiness.

NOTE: A small number of symbols will show "None" for the behavioral sub-scores (volume pressure, relative strength, expansion node) rather than a number. This happens when fewer than twenty days of historical price bars are available for that specific symbol — typically very recent listings — and the platform intentionally does not fabricate a score from insufficient history.

4.4 Scoreboard

The Scoreboard is a live leaderboard of recent signal outcomes across the scanned universe — a compact way to see, at a glance, which recent signals have played out favorably versus which have not, independent of the deeper campaign-lifecycle or divergence analysis found elsewhere in the platform.

4.5 Intelligence Change Detector

This tab runs a separate, deeper evaluation once nightly (at 12:30 AM UTC, following the day's other nightly maintenance jobs) against every symbol the Radar Screen is tracking, and compares that deeper score against the live radar score. Where the two meaningfully disagree — a difference of 15 points or more in either direction — the symbol is flagged as a divergence worth a closer look.

The Deep Evaluation Engine

The deep score is built from seven components, all computed from genuine Wyckoff, Weis, and Livermore-aligned price and volume evidence — deliberately excluding any unrelated technical-analysis methodology:

- Wyckoff structure / Weis effort-versus-result (30% weight) — real Spring, Upthrust, Buying Climax, and Selling Climax detection, based on comparing cumulative volume across successive price waves.
- Livermore line-of-least-resistance (20%) — whether price sits above both its 20-day and 50-day averages in a clean, one-directional trend.
- Campaign survival/failure evidence (15%) — how far price has pulled back from its recent high without a clean recovery.
- Volume-quality confirmation (15%) — whether volume has been heavier on advancing days or declining days over the last twenty sessions.
- Structural location (10%) — where price currently sits within its 52-week range.
- Contrary supply/distribution risk (10%) — a direct penalty when a genuine Upthrust or Selling Climax was detected, and a bonus when a genuine Spring or Buying Climax was detected.

Reading the Divergence Table

Summary tiles show total symbols audited, upgrades (deep score meaningfully stronger than the radar score), downgrades (deep score meaningfully weaker), and monitoring (a smaller disagreement, not yet at the 15-point flag threshold), along with the strongest single upgrade and downgrade of the day and the timestamp of the last completed audit. The table itself lists, per flagged symbol: price, composite (radar) score, deep score, the numeric delta between them, the previous and current classification, the transition label (Major Upgrade/Downgrade), and the current market regime.

NOTE: A result of zero flagged symbols on a given night is a legitimate, correct outcome — it means the deeper analysis genuinely agreed with the radar score for every tracked symbol that night, not that the audit failed to run.

4.6 Behavioral Intelligence

This tab tracks how you actually trade — not how you intend to trade — by scoring every completed trade you log through the Command Center's Plan Trade panel, or import through Import History, and building a longitudinal behavioral profile from the pattern.

Composite and Sub-Scores

Every completed trade contributes to five components of your profile: an overall composite decision score, an Execution score (how closely your actual entry/exit matched your stated plan — did you move your stop wider, move your target, or add size against you), a Discipline score (did you trade without a plan, or exit prematurely relative to your stated plan), a Timing score (premature exits and mid-trade timeframe changes), and a Risk Management score (position-sizing and stop-placement discipline).

Behavior Flags

Each completed trade is also tagged with a single dominant behavior flag, summarizing the clearest pattern in that trade — examples include `plan_followed`, `disciplined_execution`, `late_chase`,

premature_exit, panic_exit, plan_violated, over_sized, ignored_high_quality_signal, and revenge_trade. Your profile's "common behavior flag" is whichever tag appears most often across your recent trade history.

The Empty State

If you have not yet logged any completed trades — through the Plan Trade panel's Enter Trade and exit flow, or through a broker statement import — this tab will show: "No behavioral data yet. Start tracking trades to build your profile." This is the correct, intentional response for an account with zero recorded trade history, not an error; the profile will populate automatically as soon as real trades are recorded.

4.7 Import History

Import History accepts a CSV export of your trade history from your broker and reconstructs individual trades from the raw transaction data, feeding them into your Behavioral Intelligence profile alongside anything you log manually through the Command Center.

To use it: export your trade history from your broker (most brokers offer this under an Account History or Activity export), then drag the CSV file onto the upload area, or click to browse for it. After upload, this tab displays a summary of the reconstructed history, including total trades, win rate, and the date range covered.

4.8 Live Feed

Live Feed shows the raw real-time data stream for the currently loaded symbol — price, volume, and the underlying JSON payload as received from the live data provider — without the Command Center's analytical overlay. It exists primarily as a diagnostic and transparency tool for confirming exactly what raw data the rest of the platform is working from.

4.9 Performance

A lightweight snapshot of the currently loaded symbol's setup: current price, current setup classification, composite score, and directional bias. It is intended as a quick-glance companion to the Command Center rather than a full historical performance analysis (that longitudinal view lives in the Journal and Behavioral Intelligence tabs).

4.10 Portfolio

Portfolio shows the aggregate picture across every currently active campaign: how your total position count compares to a manageable 20-25 campaign range, a breakdown of campaigns by lifecycle state, the distribution of campaigns across Tier and ODS classifications, a list of top performers and campaigns worth watching, and any conjunction exit signals — cases where a maturing or at-risk campaign's operator dominance has fallen low enough to warrant a closer look at exiting.

4.11 Journal

The Journal is your personal trading log: open positions with their entry-quality grades, closed trades with full behavioral grades attached, a summary of your behavioral profile (patience, tendency to chase, sizing discipline, and consistency), and a form for logging a new trade directly.

4.12 Status

The Status tab (labeled Alert Status Center in the interface) is a technical, read-only dashboard of the platform's own operational health — not a trading or analytical tool. It is most useful for confirming that background data pipelines are running and current, particularly if something elsewhere in the platform looks stale.

Data Freshness

Shows the timestamp of the most recent campaign data refresh, evidence refresh, and radar scan, along with which caching mode is currently serving radar data (for example, a live scan read directly from the shared cache versus a temporary fallback).

Portfolio Intelligence

Total campaign count with a capacity indicator (Building, Optimal, or Over Capacity, based on whether the total falls within a manageable 20-25 range), Tier 1 and Tier 2 counts, average return and average Operator Dominance Score across the full campaign set, and any exit signals.

Active Campaigns, Radar Intelligence, and Opportunity Intelligence

Three side-by-side panels: a snapshot of currently active campaigns sorted by operator dominance; a compact view of the top current radar signals with their symbol, status/signal label, and score; and an "Opportunity Intelligence" panel breaking out genuinely new campaigns from the last three days, campaigns currently in the Expanding state, and an exit-watch list for maturing/at-risk positions.

Nightly Engine Schedule

A reference list of the platform's nightly background jobs and their scheduled times (Eastern Time), including geometry recalculation, the signal spark engine, campaign lifecycle state updates, the Operator Dominance Score engine, the historical analog-matching engine, the decay monitor, and the end-of-day audit that feeds the Intelligence Change Detector.

4.13 Billing

Displays your current subscription plan and provides access to Stripe's hosted billing portal for updating payment methods, viewing billing history, changing plans, or canceling a subscription. Stripe handles all payment processing directly; Sigalytic does not store payment card information.

4.14 Preferences

Customize which alert types you receive and how the platform behaves for your account. Preferences are saved to your account and persist across sessions and devices.

4.15 Admin

Restricted to platform administrators. Provides system health monitoring, user management, and platform configuration. This tab is only visible in the navigation bar for accounts with administrator access; unauthorized access attempts are logged.

4.16 Setup

Technical configuration and deployment reference information: the frontend and backend hosting details, the live data feed source, WebSocket and REST endpoint base URLs, and the environment variables the platform depends on. Primarily useful for troubleshooting connection or data feed issues.

Chapter 5 — Glossary

This glossary defines every abbreviation and piece of trading terminology used throughout the Sigmalytic V2 platform, in detail.

A+ / A / B / C / W (Grade) — The platform's outcome-quality grading scale, applied to campaigns and radar setups based on their composite score. A+ requires a score of 85 or above (the highest conviction tier); A requires 75-84; B requires 65-74; C requires 50-64; W ("Watch") or, at the very bottom of the scale, "Avoid," applies below 50 and below roughly 35 respectively. The scale is designed so that only a small minority of setups earn the top grades at any given time.

Accumulation — A Wyckoff-methodology concept describing a period in which large operators quietly build a position in a symbol, typically marked by narrowing price ranges, tests of support that fail to break down further (see Spring), and declining volume on down-moves relative to up-moves. The Intelligence Change Detector's deep engine directly looks for this pattern.

Behavioral Intelligence — The platform system that scores, tracks, and profiles a trader's own decision-making — as distinct from scoring the market itself — by comparing stated trade plans against actual execution over time.

Behavioral Transition — A label describing how a symbol's short-term market character is currently shifting — for example, "Compression to Expansion Attempt," meaning a period of tightening price range appears to be attempting to break into a genuine directional move.

BME (Behavioral Memory Engine) — A supplementary scoring engine that blends its own read of a symbol's short-term behavioral pattern into the platform's broader behavioral score component, based on recent price action, volume, and prior signal outcomes for that symbol.

Buying Climax — A Wyckoff/Weis pattern in which a sharp price advance occurs on unusually heavy volume but within a narrowing price range relative to the prior wave — historically associated with exhaustion of the immediately preceding upward move, not necessarily the end of the larger trend.

Campaign — A specific symbol that has cleared the platform's discovery thresholds (birth score, MCI, and survival score, all simultaneously) and is being actively tracked through a defined lifecycle, as distinct from every symbol the Radar Screen merely scans.

Composite Score — The single 0-100 number produced by combining a set of weighted sub-components into one overall score. Different tabs compute their own composite score from their own relevant components — the Radar Screen's composite score and the Intelligence Change Detector's deep score are deliberately built from different evidence and are not the same calculation.

Confluence — How many independently bullish (or bearish) technical signals are currently lining up together for a given symbol — for example, price trading above its volume-weighted average price, above its 20- and 50-day moving averages, and rising on above-average volume, all at once.

Conjunction Exit Signal — A flag raised when a maturing or distribution-risk campaign's Operator Dominance Score has fallen below a defined threshold, indicating that the original structural conviction behind the position has weakened enough to warrant reviewing an exit.

D3D — Internal shorthand used in some platform diagnostic contexts for decision/data/direction-related execution authorization; not a customer-facing trade signal or instruction.

Decay — A measure of how much a campaign's original structural evidence has weakened since it was first identified, expressed as a percentage where 100 represents no decay (evidence fully intact) and lower values indicate the original thesis is eroding.

Discipline Score — One of the five Behavioral Intelligence sub-scores. Reflects whether a trade was taken with a stated plan in place, and whether the trade was exited prematurely relative to that plan.

Distribution — The Wyckoff-methodology counterpart to accumulation: a period in which large operators quietly unwind a position, typically marked by failed tests of resistance (see Upthrust) and rising volume on down-moves relative to up-moves.

Divergence — A condition in which a symbol's live radar (composite) score and its deeper, once-nightly evaluation score disagree by a meaningful margin (15 points or more), flagged by the Intelligence Change Detector for closer review.

Edge Ratio — The ratio between a setup's expected favorable outcome and its expected unfavorable outcome, derived from historically similar setups — a rough measure of how much upside the historical pattern has typically produced relative to its typical downside.

Execution Score — One of the five Behavioral Intelligence sub-scores. Reflects how closely a trade's actual entry and exit matched the trader's originally stated plan — for example, whether a stop was moved wider after entry, or size was added into an adverse move.

Expansion Node — A component of the Radar Screen's composite score reflecting whether a symbol's trading range is currently compressing or expanding relative to its own recent volatility (average true range), combined with its proximity to a 52-week high.

Expected Return (ER) — The average forward return historically associated with setups that closely resemble the symbol's current conditions, used as a rough forward-looking estimate rather than a guarantee.

Gamma Flip Point — The price level at which a symbol's net options gamma exposure crosses from positive (dealer hedging tends to dampen volatility, "pinning" price) to negative (dealer hedging tends to amplify moves), derived from real options chain data when available.

GEX (Gamma Exposure) — A measure of the aggregate hedging pressure options market makers are likely to exert at a given price level, based on the options positions currently open in the market.

Historical Confidence / Historical Match Count — A measure of how many genuinely similar historical setups the platform found when estimating a setup's probability and expected return, and a corresponding qualitative confidence label (for example, Low, Moderate, High) based on how large and consistent that historical sample was.

Invalidation Level — The price level at which a setup's underlying thesis is considered compromised — a close beyond this level suggests the original read on the symbol was wrong, not merely that the trade needs more time.

Line of Least Resistance — A Jesse Livermore concept: the direction in which a security appears to be able to move with the least effort, inferred from clean trend structure (price consistently holding above both a shorter and longer moving average) combined with genuine recent momentum in that direction.

MAE (Maximum Adverse Excursion) — The worst (most unfavorable) price move a position reached at any point before its outcome was determined, historically observed across similar setups.

MCI (Market Condition Index) — One of the three thresholds a symbol must clear, alongside its birth score and survival score, before the platform will create a tracked campaign for it.

MFE (Maximum Favorable Excursion) — The best (most favorable) price move a position reached at any point before its outcome was determined, historically observed across similar setups.

ODS (Operator Dominance Score) — A 0-100 score estimating how strongly large-operator (institutional-style) buying or selling control currently characterizes a campaign, based on volume and price-structure evidence. A high ODS suggests the original accumulation or distribution thesis remains intact; a falling ODS is one of the platform's primary signals that a campaign's conviction is weakening.

Operator Control Confirmation — A distinct, more conservative confirmation state (separate from the Radar Score) that some campaign records track, indicating that operator-dominance evidence has been independently confirmed rather than merely inferred from the Radar Score alone.

Readiness Score — A 0-100 measure of how prepared a specific setup appears to be for an imminent move, combining the behavioral transition state, historical probability, and current market regime into a single "is this actually close" estimate, distinct from the underlying composite score.

Regime — The platform's classification of a symbol's current overall behavioral character — for example, Compression, Neutral, Bull Expansion, Bear Expansion, Bull Pullback, Rotation, or Trap — used as context alongside the numeric scores rather than as a score itself.

Relative Strength — A component of the Radar Screen's composite score measuring a symbol's recent performance relative to its own trend structure (for example, whether price is above a rising 20-day average which is itself above a rising 50-day average).

Risk Management Score — One of the five Behavioral Intelligence sub-scores, reflecting the appropriateness of position sizing and stop placement relative to prevailing market conditions.

Selling Climax — The bearish counterpart to a Buying Climax: a sharp price decline on unusually heavy volume within a narrowing range relative to the prior wave, historically associated with short-term exhaustion of the immediately preceding downward move.

Spring — A Wyckoff pattern in which price briefly breaks below an established support level on relatively light volume and quickly recovers back above it — interpreted as a test that shakes out weak holders without genuine new selling pressure, historically a bullish accumulation signal.

Structural Location — Where a symbol's current price sits within its own 52-week trading range, used as one input into the deeper Wyckoff/Weis/Livermore evaluation — proximity to the top of the range is treated as strength context, proximity to the bottom as weakness context.

Survival Score — One of the three thresholds a symbol must clear before becoming a tracked campaign, and a metric that continues to be tracked afterward as a measure of whether a campaign is holding together over time.

Tier 1 / Tier 2 — The platform's highest and second-highest conviction classifications for a tracked campaign, corresponding to the A+ and A outcome-quality grades respectively.

Three-Bar Reversal — A short-term price pattern spanning three consecutive bars that historically precedes a change in short-term direction, detected directly from recent daily price bars.

Timing Score — One of the five Behavioral Intelligence sub-scores, reflecting whether a trade's entry and exit timing (relative to the trader's own stated plan) showed premature exits or mid-trade changes of mind.

Upthrust — The bearish counterpart to a Spring: price briefly pushes above an established resistance level on relatively light volume and quickly fails back below it — interpreted as a false breakout that traps new buyers, historically a bearish distribution signal.

VSA (Volume Spread Analysis) — A tape-reading discipline, closely related to Wyckoff and Weis methodology, that reads the relationship between a price bar's range (spread), its volume, and its closing position within that range to infer whether genuine buying or selling effort is behind a move.

Volume Pressure — A component of the Radar Screen's composite score measuring whether current trading volume is unusually heavy relative to a symbol's own recent average volume, combined with the direction of the current price move.

VWAP (Volume-Weighted Average Price) — The average price a symbol has traded at over a given session, weighted by the volume traded at each price — a common reference level for whether current price is trading rich or cheap relative to the session's actual activity.

Weis Wave — David Weis's volume-analysis methodology, which measures cumulative volume across successive price swings (waves) to read the balance of buying and selling effort, used as the foundation of the platform's Spring/Upthrust/Climax detection.

Wyckoff Method — Richard Wyckoff's early-20th-century framework for reading the footprints of large operators in price and volume behavior — the foundational methodology behind the platform's campaign-lifecycle concept and its deeper (Intelligence Change Detector) evaluation engine.

Chapter 6 — Support and Feedback

How to Get Help

If you encounter a problem with the platform, need clarification on a feature, or have a question not answered in this guide, reach out directly:

Email Support

greg.kosmala@gmail.com

Please include your account email, a description of the issue, and if possible a screenshot or the exact text of any error message you see.

Beta Feedback

The most valuable feedback includes: features that are not working as expected, features that work but could be meaningfully improved, features that are missing that would materially change how useful the platform is, and — most importantly — any moment where the platform led to a worse trading decision than you would have made without it. That last category should always be reported immediately.

Appendix A — Worked Examples

The six walkthroughs below show concrete, step-by-step ways to use the platform for common tasks. Each one references the real tabs and panels described in Chapter 4.

Example 1 — Finding and Confirming a Fresh Opportunity

Goal: identify a promising setup you weren't already watching, and decide whether it's worth acting on.

- Open the Radar Screen and look at the Top Opportunities section at the top of the tab — these are the highest-readiness setups the system has already assembled full evidence for.
- Pick a symbol with a high readiness score and an "Armed" or "Setting Up" state. Read its evidence card: probability, edge ratio, expected return, grade, and the "Why This Trade?" explanation.
- Type the symbol into the Command Center's symbol field and click Load Symbol. Review the Trade Card, Price Ladder, and — if available — the gamma overlay on the chart, to see whether the deeper structural picture agrees with what the Radar Screen surfaced.
- If you decide to act, fill out the Plan Trade panel (direction, entry, stop, target, size, and a short thesis note) and click Save Plan before doing anything else. This is the step that makes the trade traceable in your Behavioral Intelligence profile later.

Example 2 — Reviewing an Overnight Divergence

Goal: understand why the Intelligence Change Detector flagged a symbol, and decide whether the flag changes your view of it.

- Open the Intelligence Change Detector first thing before the market opens. Check the Last Audit timestamp to confirm you're looking at last night's completed run, not a stale result.
- Find the flagged symbol in the table. Compare its Composite (radar) score against its Deep score, and read the Delta and Transition columns — a Major Downgrade means the deeper Wyckoff/Weis/Livermore evaluation is meaningfully more skeptical than the surface radar score; a Major Upgrade means the opposite.
- If the symbol is one you already hold or were planning to enter, load it into the Command Center and re-examine the Price Ladder and current regime before making any changes to your position or plan.
- If the symbol is new to you and shows a genuine Major Upgrade, consider adding it to your watchlist for the next session rather than acting on the flag alone — the Intelligence Change Detector is a comparison signal, not a standalone trade instruction.

Example 3 — Following a Campaign Through Its Lifecycle

Goal: track a specific symbol's structural story over time, rather than treating each day's price move as a separate event.

- In Campaign Intelligence, use the Yellow Alert banner or the SPARK tab to find a newly discovered campaign.

- Note its starting ODS, Decay, and outcome grade. Because a genuinely new campaign may not yet have enough history for a full ODS calculation, you may initially see "ODS PENDING — INSUFFICIENT HISTORY"; this is expected, not an error.
- Check back on the same symbol every few sessions. Watch for its lifecycle state to progress (SPARK to SURVIVING to EXPANDING, for example), and watch its ODS and Decay values for signs of strengthening or weakening conviction.
- If the campaign later drifts into MATURING or DISTRIBUTION_RISK with a falling ODS, treat that as your cue to revisit the position (see Example 6 for the exit-focused version of this workflow).

Example 4 — Planning, Entering, and Exiting a Trade

Goal: use the Plan Trade panel correctly so the trade contributes meaningfully to your Behavioral Intelligence profile.

- Before entering, fill out every field in the Command Center's Plan Trade panel: Direction, Entry Price, Stop, Target, Size, and a short Setup Notes description of your thesis.
- Click Save Plan. This records your stated intention without opening a live position.
- When you actually take the trade, click Enter Trade. From this point, the platform is tracking your live execution against the plan you just stated.
- When you exit, log the exit through the same panel. Your Behavioral Intelligence tab will then reflect this trade's Execution, Discipline, Timing, and Risk Management scores, along with a dominant behavior flag (for example, disciplined_execution or premature_exit) describing the clearest pattern in how the trade actually played out.

Example 5 — Rebuilding Your Behavioral Profile from Broker History

Goal: give the Behavioral Intelligence system your complete trading history, not just trades logged manually going forward.

- Export your trade history as a CSV from your broker's account activity or history page.
- Open Import History and drag the CSV file onto the upload area, or click it to browse for the file.
- Review the resulting summary: total trades reconstructed, win rate, and the date range covered.
- Open Behavioral Intelligence and confirm your Total Trades count and composite score now reflect the imported history alongside anything you had already logged manually.

Example 6 — Deciding Whether to Exit a Weakening Position

Goal: use the platform's own signals to inform an exit decision, rather than relying on price action alone.

- In Portfolio or Status, check the Exit Signals / Conjunction Exit Signal count. A non-zero count means at least one MATURING or DISTRIBUTION_RISK campaign has fallen below the Operator Dominance threshold the platform uses to flag weakening conviction.
- Open Campaign Intelligence and find the specific flagged symbol. Compare its current ODS and Decay against where they stood earlier in the campaign's life.
- Cross-check the same symbol against the Intelligence Change Detector — a simultaneous Major Downgrade there adds independent, deeper-methodology weight to the same conclusion.

- If you decide to exit, log it through the Plan Trade panel's exit flow so the decision — and its eventual outcome — feeds back into your Behavioral Intelligence profile.
